

Move and Learn Motor Skill Development App

User Testing

Introduction

Move and learn motor skill development is for people with eye and hand coordination problems, and the goal of this user testing is to evaluate usability, effectiveness, and engagement for motor skill improvement.

Ibrahim's Background:

Ibrahim is a 19-year-old boy living in Germany with mild cerebral palsy, which mainly affects his left arm and leg, leading to coordination difficulties. The family relocated to Germany three years ago and receives government support, including regular consultations with physical therapists, access to assistive devices, and medical care.

At home, his mother takes charge of daily therapy sessions and uses digital apps to guide and support their routine.

Ibrahim's Experience:

After playing the game, Ibrahim was visibly excited and happy. From the moment he started interacting with the game, his face lit up with joy and curiosity. He smiled brightly and showed genuine interest in exploring the features of the game. It was heartwarming to see how engaged he became, focusing on each part of the activity with enthusiasm. Ibrahim's positive reaction reflected not only his enjoyment but also the comfort and confidence the game gave him. It was clear that the game made him feel included, empowered, and appreciated.

Objectives of Testing:

The objective of this experiment was to evaluate whether the physical activities within the game are appropriately designed for users with coordination difficulties, and to assess the overall user experience. Specifically, the experiment aimed to determine if the user could understand the instructions clearly, whether the interactive elements of the game were encouraging and motivating, and how the user responded to the interface and setup. By observing Ibrahim's interaction with the game, the goal was to assess the game's effectiveness in promoting eye-hand coordination, its clarity in guiding users through tasks, and its ability to provide a positive and engaging experience for individuals with mild cerebral palsy.

Conclusion:

Based on the observations and results of the experiment, it was evident that the game successfully engaged Ibrahim and supported his motor skill development. He was able to follow the instructions without difficulty, and his active participation demonstrated that the physical activities were well-suited to his abilities. User feedback was highly positive. He expressed enjoyment and showed enthusiasm throughout the session. His reactions indicated that the game made him feel encouraged, included, and confident. Overall, the usability of the game was effective, with an intuitive interface and engaging design that held his attention. The game proved to be a valuable and accessible tool for promoting motor skill improvement in users with coordination challenges, such as mild cerebral palsy.
